

Mechanical and Biological Properties of Silk Fibroin/Carbon Nanotube Nanocomposite Films

Caixia Pan, Qifan Xie, Zeyun Hu, Mingying Yang, and Liangjun Zhu*

Abstract: Multi-walled carbon nanotubes (MWCNTs) were homogeneously dispersed in silk fibroin (SF) solutions at different compositions, and a simple solvent-casting method was used to fabricate SF/MWCNT films. Structure, viscosity, and mechanical properties of the SF/MWCNT nanocomposites were characterized by FTIR (Fourier Transform Infrared Spectroscopy), viscometry, and tensile testing. Fibroblast cells were used to examine cell viability and attachment to nanocomposite films. Compared to a pure SF film, adding just 0.5% (w/w) of MWCNT to the SF matrix could enhance the Young's modulus and ultimate tensile strength by approximately 24% and 39%, respectively. In addition, with increasing matrix content, the cell viability and attachment to nanocomposite films were significantly improved. These results indicate that CNTs are one of the most useful nanoscale agents for material property reinforcement because of their extraordinary mechanical, electrical, and thermal properties [1-6]. CNTs have shown controversial and complex properties. Pristine CNTs have displayed cytotoxicity on certain cell lines, which can be attributed to the use of metal catalysts, such as nickel, during CNT fabrication [7]. Conversely, CNTs incorporated with biopolymers have shown great biocompatibility [8-10]. Despite the growing debate over the cytotoxicity of CNTs, these previous publications demonstrate why interest in this field has doubled in recent years [11].

Silk is a natural protein that has been widely used as a biomaterial for many years. Due to its flexible nature, biocompatibility, and

Silk Fibroin Purification

0.1 g of silk fibroin was dissolved in 10 mL of 0.05 M sodium carbonate solution. The solution was filtered and the residue was washed with distilled water. The combined filtrate and washings were dialyzed against distilled water for 48 h. The dialysate was concentrated under reduced pressure and the residue was lyophilized. The yield of purified silk fibroin was 0.09 g (9%).

SF/MWCNT Nanocomposite Film Fabrication

The SF/MWCNT nanocomposite film was prepared by the casting method. A solution of SF (0.1 g) and MWCNT (0.01 g) in 10 mL of distilled water was casted on a glass plate. The film was dried at room temperature for 24 h. The film was then dried in a vacuum oven at 60 °C for 24 h. The film was then stored in a desiccator. The film was characterized by FTIR, SEM, and AFM. The FTIR spectra of the SF/MWCNT nanocomposite film showed characteristic absorption bands of SF and MWCNT. The SEM images of the SF/MWCNT nanocomposite film showed a smooth surface. The AFM images of the SF/MWCNT nanocomposite film showed a uniform thickness.

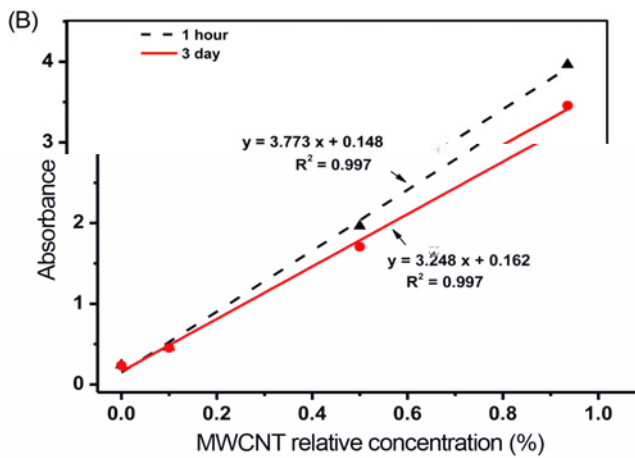

Figure 1. (A) SF/MWCNT nanocomposite solutions of different MWCNT compositions (M1, M2, M3 represent 0.1 % (w/w) MWCNT, 0.5 % (w/w) MWCNT, 1 % (w/w) MWCNT respectively) after 3 days, and MWCNTs in water (Water/M) after only 1 h. (B) Absorbance of SF/MWCNT solutions as a function of relative MWCNT concentration of after 1 h and 3 days in a stationary position.
